## **Abstract**

Making use of a newly constructed data set of good and bad news, we investigate a set of behavioral and efficient market hypotheses about the responses of the Korean stock market with regard to good and bad news during the global financial crisis. Even though the Korean market over this period passes a number of the standard efficient market tests, we found several interesting behavioral aspects of market behavior. The market typically responded substantially more strongly to bad than to good news and this held in both rising and falling markets. We also found results that are consistent with optimism and confirmation biases with the market that appear to pay less attention to bad news during rising periods. The effects of good news were stronger in down rather than in up markets. While inconsistent with confirmation bias, this is consistent with the view that down markets act as a wake up call that stimulates the market to pay more attention to news in general. We found mixed support for the rational expectations hypothesis that only unanticipated news should affect the market. We developed proxies for anticipated and unanticipated news and found that while anticipated news often had significant effects, unanticipated news had much larger effects. We also found that all of the large market moves occurred on days of important news, which is consistent with the efficient markets views. Thus, we conclude that both efficient market and behavioral finance hypotheses can be useful in explaining market behavior.

## **I. Introduction**

The recent rash of asset market bubbles and bursts has generated increased interest in the debate over the efficiency of stock market behavior. Recently, beliefs in the efficient market hypothesis (EMH) have been challenged by the global financial crisis and the growing literature on behavioral finance. Debates on this topic, however, often fail to take sufficiently into account that there are at least two versions of the EMH.

One is that it is impossible (or at least extremely difficult) for investors to systematically beat the market. A second and much stronger version is that markets are not subject to serious biases. While it has often been assumed that the first version implied the second, this is not necessarily the case. Even if the first version holds that markets may be subject to some of the types of biases pointed out in the literature on behavioral finance, as long as they do not occur in such a mechanically consistent way that they offer systematically exploitable profit opportunities.

While early studies of the Korean stock market found signs of inefficiencies<sup>1</sup>, it seems reasonable that the efficiency of the market would increase over time as the market becomes more fully developed. Despite the stresses generated by the global financial crisis, in recent research Kim (2013) found that the Korean stock market passes a number of standard tests for market efficiency.<sup>2</sup> Furthermore, Narayan and Smyth (2004) tested the efficient market hypothesis using monthly South Korean stock price data for the period 1981-2003. KOSPI was consistent with the efficient market hypothesis.<sup>3</sup>

In this paper, we investigate whether despite behaving in a manner consistent with weak form efficiency, the Korean stock market displays other interesting behavioral characteristics. Drawing on the rapidly expanding literature on behavioral and neuro finance, we investigate several aspects of the Korean stock market's reaction to news during the global financial crisis. For this purpose we constructed a new data set on foreign and domestic financial and economic news for this time period and test several hypotheses about the reactions of financial markets to both good and bad news. We found support for the hypothesis that the market responds more strongly to bad than to good news during a crisis period but that this relationship doesn't hold consistently across periods of market upswings and downswings during the crisis period.

We also test for the standard efficient market, the rational expectations assumption that the market reacts only to unanticipated and not anticipated news. We find some support for a weak form of this hypothesis where the market reacts to our measures both of expected as well as unexpected news, but the response to unexpected bad news is much larger than for expected

---

<sup>2</sup> Kim (2013) applied the Augmented Dickey-Fuller (ADF) test, Autocorrelation Function (ACF) test, Runs test, and Variance Ratio Test to the behavior of the KOSPI in recent years only, in particular, from August 1, 2007 through March 31, 2010.

<sup>3</sup> Narayan and Smyth (2004) applied Augmented Dickey-Fuller (ADF) test. They concluded that stock prices for South Korea had a unit root during the research term.

news. For good news, the differences were much smaller. We also test the hypothesis from complexity economics and behavioral finance that contrary to the rational expectations hypothesis, there may be large market moves even in the absence of major news. We do not find support for this view over the time period investigated.

In the following section, we explain the behavioral hypotheses that we test. Section 3 discusses our development of the data set for news. Section 4 tests the hypotheses, and Section 5 offers some concluding remarks.

## **II. The Behavioral Hypotheses**

Behavioral and neuro finance focuses on cognitive limitations of the human brain that can lead individuals to make decisions that conflict with rational choice.<sup>4</sup> The result is a number of hypotheses about biases in financial market behavior. Some of the most commonly found biases from research in cognitive psychology and neuroscience are tendencies toward hubris, i.e. over optimism about our abilities, propensities to avoid the recognition of uncertainty by putting excessive faith in strong views of the world, and confirmation biases that lead to putting excessive weight on observations that confirm our prior views and discounting those that conflict. These all seem to be quite human tendencies albeit ones that conflict with our assumptions about pure economic man.

Confirmation bias may apply not only to our weighing of evidence about the correctness of the specific mental models that are used to interpret and predict market behavior, but also can interact with respect to general moods of optimism and pessimism. Thus, we may largely ignore

---

<sup>4</sup> See, for example, Akerlof, G. A. and R. J. Shiller (2009); Burnham, T. (2005); Cohan, W. D. (2009); Fox, J. (2009); Montier, J. (2002); Peterson, R. L. (2007); Shefrin, H. (2000); Shleifer, A. (2001); and Zweig, J (2007).

specific pieces of bad news in good times while placing great weight on them in bad times and vice versa.

Considerable research in cognitive psychology has documented that on average people are strongly biased toward over optimism, even though some are excessively pessimistic.<sup>5</sup> The biased behaviors of particular groups of individuals do not necessarily show up in market prices. Advocates of the efficient market view have always recognized that not all market participants will behave rationally, but assume that rational speculators will arbitrage the effects of their actions out. Where there are “limits to arbitrage,” however, such biases may not always be cancelled out.

Of course, thinking that a hypothesis seems plausible does not assure that it is important in practice. We view the behavioral finance approach that offers us a rich set of hypotheses to test. We would expect to find that some of these hypotheses are empirically important while others are not and as with the efficient market hypotheses, their relevance may vary in different situations. Here we test several hypotheses.

The first is that in periods of crisis bad news would have stronger effects on the market than good news. This has been previously tested for the Asian crisis with somewhat conflicting findings. Kaminsky and Schmaker (1999) found a sizably stronger reaction to bad news during the Asian crisis for the days of greatest changes in dollar value in the set of nine Asian stock markets. However, Jo and Willett (2000) found little support for the hypothesis that the Asian currency crisis was dominated by panic in the markets such that investors and speculators reacting much more strongly to bad rather than good news. Thus, we view this possible bias as an open question.

---

<sup>5</sup> See Sharot (2011)

We further test whether in rising markets if market optimism and confirmation bias leads the market to pay more attention to good news than to bad, while in declining markets, the climate of pessimism leads markets to pay more attention to bad news than to good news. We also construct proxies for anticipated and unanticipated news to test the rational expectations hypothesis, that only unanticipated news moves the market.

### **III. The Data Set of News<sup>6</sup>**

Data were collected from August 1, 2007 through March 31, 2010. The first date was chosen based on the election of a new and somewhat controversial Korean government. While evidence of the subprime mortgage crisis in the United States had begun to become public by then, the magnitude of the problem was not appreciated and it was not until after the failure of Lehman Brothers that expectations emerged that the crisis would spread to the emerging market countries. There is no generally agreed date for the ending of the crisis and this almost certainly varied from country to country. On March 20, 2010, the Korean government officially declared that the economic crisis was over, so we used March 31, 2010 as the end date for our sample.

The data set on news is presented in the appendix. It was collected from three major Korean business newspapers on a daily basis: Maeil Business Newspaper, Seoul Business Newspaper, and Hankook Business Newspaper. The front and second page of the newspapers were checked and the one most important news item was chosen day by day. In order to be sure to focus only on important news, the daily news item that was chosen must have been located on the front or second page (top 20 economy and business news on the day) of all three newspapers. If there were multiple news items that satisfied our standard of substantial news, the news from

---

<sup>6</sup> This data set was constructed by Yoonmin Kim as a part of his dissertation research under the direction of Professor Willett.

the crisis timeline of events and policy actions from the Federal Reserve Bank of Saint Louis was chosen.

Our classification of good and bad news follows Baig and Goldfajn (1999) and Jo and Willett (2000). Examples of good news are credible economic reforms, upgraded credit ratings, the removal of capital controls, good economic indicators (such as lower inflation rate, trade surplus, and so on), financial aid agreements, news forecasts of a better economic outlook, and political stability.

Bad News includes financial troubles or bankruptcies of firms, non-credible economic reforms, downgrades in credit ratings, reports that indicated conflicts with international organizations, the imposition of capital controls, and worse than expected economic indicators (such as a higher inflation rate, and so on). News items that could not be defined clearly were excluded. The financial information came from S&P, Google Finance, KOSIS (Korean Statistical Information System), KOSCOM (Korea Securities Computing Corporation), and the Korean Stock Exchange Database.

Of course the news that we have coded may not have been the only factor influencing stock price movements that day. To control for regional or global developments that might influence the KOSPI, we also calculate returns adjusted for returns of the S&P Global 1200 index and MSCI\_EM index.<sup>7</sup> It does not seem clear whether the adjusted or unadjusted returns

---

<sup>7</sup> S&P Global 1200 Index, which is a free-float, weighted stock market index of global equities from Standard & Poor's. The index covers 31 countries and approximately 70% of global stock market capitalization. The S&P Global 1200 is comprised of seven regional indices: the S&P 500; S&P/TSX 60 (Canada); the S&P Latin America 40 (Mexico, Brazil, Argentina, Chile); the S&P/TOPIX 150 (Japan); the S&P Asia 50 (Hong Kong, Korea, Singapore, Taiwan); the S&P/ASX 50 (Australia) and the S&P Europe 350. The European index is divided into three sub indices: the S&P Euro, covering the Euro zone markets; the S&P Euro Plus, adding Denmark, Norway, Sweden, and Switzerland; and the S&P United Kingdom. For the emerging markets control Google Finance was used to obtain the MSCI\_EM. MSCI\_EM that is designed to measure the equity market performance of 21 emerging markets. The MSCI\_EM consists of the following 21 emerging market country indices: Brazil, Chile, China, Colombia, Czech Republic, Egypt, Hungary, India, Indonesia, Korea, Malaysia, Mexico, Morocco, Peru, Philippines, Poland, Russia, South Africa, Taiwan, Thailand, and Turkey.

are most relevant and for the adjustments, whether the global or EM index is most appropriate. Likely, this will vary from one type of news to another. Thus, we report all three estimates. Fortunately, there turns out to be little difference in the stories they tell.

Of course, in efficient markets, rational expectations models news is "news" only if it is unanticipated. We thus developed a coding that distinguished between anticipated and unanticipated news. In order to determine which news is expected or unexpected, soft news items such as rumors and discussions of possible future policy actions were excluded and only hard news such as policy actions and data releases were checked. We read all of the hard news articles. If there was related soft news a few days before the hard news, the hard news was considered "expected news." If there was no soft news related to the hard news or the soft news was totally opposite from later hard news, the hard news was considered "unexpected news." Since each central bank in each country announces interest rate adjustments on a specific day, most of the news related to interest rate adjustments are considered "expected news."<sup>8</sup> However, we read all of the news articles one by one and if there was any nuance that the interest rate adjustment was a surprise, we categorized the news as "unexpected news." Fortunately, there was no ambiguous news to try to figure out after applying these methods.

#### **IV. Results on News and the Behavioral Hypotheses**

- **Hypothesis 1: Investors in KOSPI react more strongly to bad news than good news during a crisis period.**

For the first tests, we examined the impact effects of all forms of good and bad news on the KOSPI. OLS regression methodology was employed for KOSPI's own return on news. Each

---

<sup>8</sup> For example, the Bank of Korea determines the central interest rate on the second Thursday of each month. In the case of FRB, FOMC determines the federal interest rate every six weeks on Tuesdays (8 times a year).

piece of news is considered an event and abnormal return patterns are checked after the news events.

$$KOSPI\_R_t^i = \beta_1 GN_t^i + \beta_2 BN_t^i + \beta_3 NN_t^i + \varepsilon_t^i$$

As shown in Table 1, for own returns a substantially larger effect of bad than good news, was found, 1.83 versus 1.46 percent. As expected, looking at the changes in the KOSPI relative to other market indices yielded smaller coefficients, implying that the Korean and foreign stock markets typically moved in the same directions, but the differences between good and bad news remained statistically significant.

• **Hypothesis 2: Investors in KOSPI react more strongly to bad news in negative momentum and to good news in positive momentum.**

Next, since the period covered displayed both an up and down swing we were able to test the hypotheses concerning differential reactions to good and bad news during rising versus falling markets as a type of test of confirmation bias. This hypothesis suggests that markets would pay more attention to the news that fits with their prior expectations so that bad news would have less impact than good news during an upswing while it would have less effect during a down turn.

In order to find positive and negative momentum, we checked the difference between KOSPI 200 index and KOSPI 200 Future index (KOSPI Future one-month) to decide the daily momentum. Also, we divided the market into periods (one week and one month) of general rise and general fall.

Among the three measures, one month trends were employed to delineate rising and falling markets because one month trends show the result of this research most clearly.

$$KOSPI\_R_t^i = \beta_1(GN_t^i * PM_t^i) + \beta_2(GN_t^i * NM_t^i) + \beta_3(BN_t^i * PM_t^i) + \beta_4(BN_t^i * NM_t^i) + \beta_5(NN_t^i * PM_t^i) + \beta_6(NN_t^i * NM_t^i) + \varepsilon_t^i$$

(Figure 1 about here)

As we see in Table 2, the results for the KOSPI's own effects and those adjusted for the other indices are qualitatively similar. Bad news continues to have stronger effects than good news under both rising and falling markets, but the difference is less in rising than falling markets, 16 versus 36 basis points for the own returns. This offers some support for the existence of confirmation bias. The effects of bad news are substantially greater in downward than upward moving markets, 1.99 versus 1.46%, which is also consistent with the hypothesis. However, the effects of good news in rising markets is smaller than the effects of good news in falling markets, 1.63 versus 1.30 percent, a difference of 33 basis points which is inconsistent with the confirmation bias hypothesis.

This finding is consistent, however, with another behavioral hypothesis -- that in boom markets investors get lazy and pay less attention to news, while down markets act as a wake up call and investors pay more attention to both good and bad news. With optimistic views deflated, views may be held less strongly, leading to a reduction in confirmation bias and hence more attention to both good and bad news<sup>9</sup>. This is overlaid with the hypothesized tendency for market participants to react more strongly to bad news in bad times that is consistent with a general switch in the market from optimism to pessimism.

---

<sup>9</sup> Such behavior is consistent with the hypothesis developed by Willett et al. (forthcoming) that financial markets tend to pay too little attention to developing problems during good times and behave more closely to rational expectations during crises.

The statistical significance of the coefficient difference was also checked in this study. As seen in Table 2, in the case of good news, the differential between good momentum and bad momentum was significant only in the returns adjusted with S&P Global 1200. In the case of bad news, the differential was significant in all the cases. However, the significances in KOSPI's own return and returns adjusted with MSCI\_EM were higher than the returns adjusted with S&P Global 1200. This shows that emerging markets reacted with more insensitivity to momentum in the case of good news and more sensitively to momentum in the case of bad news rather than in other countries.

• **Hypothesis 3: Investors in KOSPI react more strongly to unexpected news than expected news.**

$$\begin{aligned}
 KOSPI\_R_t^i = & \beta_1(HPGN_t^i * E_t^i) + \beta_2(HPGN_t^i * UE_t^i) + \beta_3(HPBN_t^i * E_t^i) + \\
 & \beta_4(HPBN_t^i * UE_t^i) + \beta_5(HDGN_t^i * E_t^i) + \beta_6(HDGN_t^i * UE_t^i) + \beta_7(HDBN_t^i * E_t^i) \\
 & + \beta_8(HDBN_t^i * UE_t^i) + \varepsilon_t^i
 \end{aligned}$$

As shown in Table 3, in all of the categories of news, the impact of unexpected news was much stronger than expected news except in the case of bad-hard-policy news. This latter result is likely because the sample size was too small to offer reliable results. There were 13 pieces of news in the unexpected bad-hard-policy news, but only 5 pieces of news in the expected bad-hard-policy news. The statistical significance of the coefficient difference was also checked in this study. The good-policy news with an expected-unexpected differential was significant at the 5 percent level while bad-policy news with an expected-unexpected differential was not significant.

Next, we considered the effects of momentum. Since two parameters (positive momentum and negative momentum) are added, there are four cases. As shown in Table 4, if the policy

announcement news is in a different direction from the momentum, such as good news with negative momentum or bad news with positive momentum, the impact of unexpected news was stronger than expected news. However, if the policy announcement news is the in same direction as the momentum, such as good news with positive momentum or bad news with negative momentum, the impact of expected news was stronger than unexpected news except in the case of the KOSPI's own return test (good news with positive momentum).

As shown in Table 3, in the case of good news, the statistical significance of the coefficient difference was very significant in KOSPI's own return. Since a lot of news is from good policy announcements from Korean domestic news, and the Korean stock market is highly market efficient, the response between expected news and unexpected news should be significantly different. In the case of bad news, the differential was not significant in any of the cases because of the small sample size.

• **Hypothesis 4: Contrary to efficient market theory, there can be large market moves in the absence of news.**

Several studies have found that for the U.S. stock market, many of the largest price movements occurred when there was no major news, suggesting that important internal dynamics were at work.<sup>10</sup> This conclusion did not hold up for the Korean stock market over the period we investigated. There was substantial news on 367 news days among 667 business days during the research period. There were 188 days with good news (51.2 percent) and 179 days with bad news (48.8 percent). We took the largest 25 movements in each direction.<sup>11</sup>

---

<sup>10</sup> See Cutler, Poterba, and Summers (1991) and Fair (2002).

<sup>11</sup> The smallest of the each movements turned out to be +3.3 percent and -3.3 percent respectively.

## V. Concluding Comments

Making use of a newly constructed data set of good and bad news, we have investigated a set of behavioral and efficient market hypotheses about the responses of the Korean stock market to good and bad news during the global financial crisis. We found strong evidence for our conjecture that even in markets that pass efficient market tests, which the Korean market did over this period, there can be interesting behavioral aspects of market behavior to explore. Our findings support our belief that both the efficient market hypothesis and behavioral approaches should be part of any financial researcher's tool kit. There should not be a strong division between the use of one approach or the other.

One of our most interesting findings is that over the period studied, the Korean Stock market responded considerably more strongly to bad than good news and that this held in rising as well as falling markets. Of course, it is possible that over this period the bad news tended to be more important than the good news. Generally, accepted metrics have not yet been developed to distinguish the relative importance of different types of news although undoubtedly there are often important differences. Attempting to adjust for such differences must await further research. Still, we find this result interesting, as we have no prior reason for believing that the bad news over the period was systematically more important than the good news.

Another interesting finding is that declining markets responded more strongly to both good and bad news than did rising markets. This is consistent with the hypothesis put forward in behavioral and neuro finance literature that in rising markets investors are often heavily influenced by over optimism and hubris and that they understand what is going on to a much higher degree than is warranted and as a result, they pay little attention to both good and bad news. On the other hand, in slumping markets many investors may be less certain in their views

about how well they understand what is going on in the market and hence pay more attention to both good and bad news expectations more when assessing news.

We have investigated here only a few of the behavioral hypotheses that are being developed in the research on behavioral and neuro finance. Thus, a great deal of further work can be done to test other hypotheses as well as considering different time periods, countries, and types of markets.

Figure 1. Weekly and Monthly Trend of KOSPI

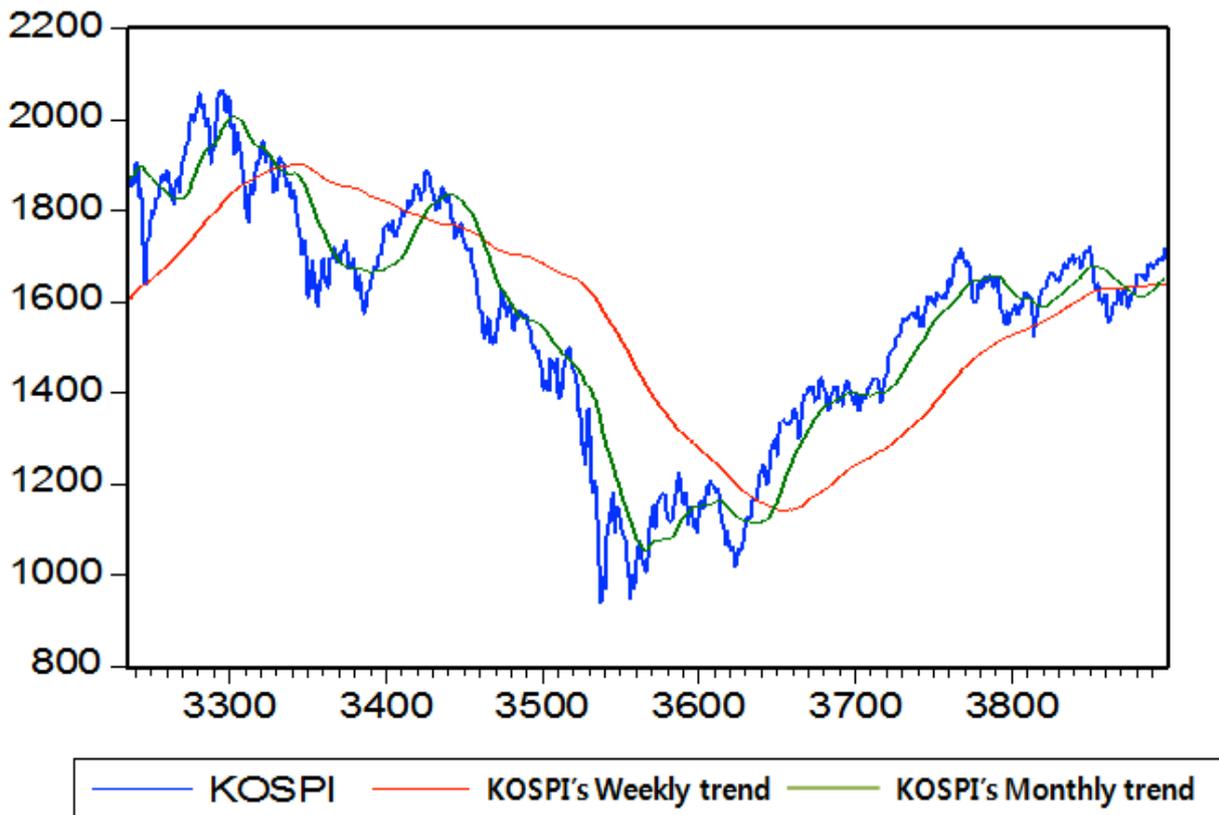

Table 1. The Impact Effects of Good and Bad News on the KOSPI

Event	KOSPI's Own Return (1)	Returns adjusted with Global Index (S&P G1200) (2)	Returns adjusted with Global Index (MSCI_EM) (3)	Number of Observations
Good News	1.46% *** (13.13)	1.22%	1.23%	188
Bad News	- 1.83% *** (-16.11)	- 1.55%	- 1.56%	179
the significance tests for the differences between the coefficients	***  (100%)	***  (100%)	***  (100%)	

\*\*\* statistical significance at 99%, \*\* 95%, and \*90%, respectively

Table 2. The Impact Effects of News with Momentum on the KOSPI

Event	KOSPI's Own Return (1)	Returns adjusted with Global Index (S&P G1200) (2)	Returns adjusted with Global Index (MSCI_EM) (3)	Number of Observations
Good News with Positive Momentum	1.30% <sup>***</sup> (8.38)	1.04%	1.08%	98
Good News with Negative Momentum	1.63% <sup>***</sup> (10.18)	1.42%	1.39%	90
the significance tests for the differences between the coefficients	Not Significant (82.72%)	* (90.61%)	Not Significant (83.97%)	
Bad News with Positive Momentum	- 1.46% <sup>***</sup> (-7.08)	- 1.22%	- 1.20%	54
Bad News with Negative Momentum	- 1.99% <sup>***</sup> (-14.68)	- 1.70%	- 1.72%	125
the significance tests for the differences between the coefficients	** (95.3%)	* (93.75%)	** (96.16%)	

\*\*\* statistical significance at 99%, \*\* 95%, and \*90%, respectively

Table 3. The Impact Effects of Expected and Unexpected Policy Announcement News on the KOSPI

Event	KOSPI's Own Return (1)	Returns adjusted with Global Index (S&P G1200) (2)	Returns adjusted with Global Index (MSCI_EM) (3)	Number of Observations
Policy News (Good) Expected	1.26% *** (3.54)	1.19%	1.17%	22
Policy News (Good) Unexpected	2.33% *** (8.15)	1.90%	1.90%	34
the significance tests for the differences between the coefficients	** (98.04%)	Not Significant (88.99%)	* (90.68%)	
Policy News (Bad) Expected	- 0.66% (-0.89)	- 0.92%	- 0.97%	5
Policy News (Bad) Unexpected	- 0.84% * (-1.83)	- 0.73%	- 0.81%	13
the significance tests for the differences between the coefficients	Not Significant (16.36%)	Not Significant (17.1%)	Not Significant (14.44%)	

\*\*\* statistical significance at 99%, \*\* 95%, and \*90%, respectively

Table 4. The Impact Effects of Expected and Unexpected Policy Announcement News with Momentum on the KOSPI

Event	Expected or Unexpected	KOSPI's Own Return (1)	Returns adjusted with Global Index (S&P G1200) (2)	Returns adjusted with Global Index (MSCI_EM) (3)	Number of Observations
Good News * Positive Momentum	Expected	1.66% <sup>**</sup> (2.63)	1.45%	1.42%	12
	Unexpected	1.87% (1.12)	1.21%	1.22%	10
Good News * Negative Momentum	Expected	0.78% <sup>***</sup> (2.71)	0.89%	0.87%	10
	Unexpected	2.51% <sup>***</sup> (5.64)	2.19%	2.19%	24

\*\*\* statistical significance at 99%, \*\* 95%, and \*90%, respectively

## Appendix: KOSPI's Significant News

Date	CODE	CAR	t-value	Significance	NEWS
08/01/07	NSB NFB	-0.0392	-3.1408	***	Subprime woes
08/10/07	NHDB NFB	-0.0335	-3.4450	***	The fallout from the U.S. subprime mortgage crisis Friday is spreading worldwide
